Assignment-9.2

Task Description -1 (Documentation – Function Summary Generation)

Code used:

```
def factorial(n):  
    if n == 0:  
        return 1  
    else:  
        return n*factorial(n-1)  
factorial(5)
```

Prompt:

Add a short summary describing the purpose of the function in the code

Output:

The screenshot shows a Jupyter Notebook cell with the following code:

```
[1] def factorial(n):  
    # This function calculates the factorial of a non-negative integer using recursion.  
    if n == 0:  
        return 1  
    else:  
        return n*factorial(n-1)  
  
    factorial(5)
```

The output of the cell is 120, indicated by the text "120" at the bottom of the cell.

Task Description -2 (Documentation – Logical Explanation for Conditions and Loops)

Code Used:

```
def numbers(n):  
    if n > 0:  
        result = "Positive"  
    elif n < 0: result =  
        "Negative" else:  
        result = "Zero"  
    return result  
numbers(3)
```

Prompt: explain only decision-making logic
and loop behavior inside the code Output:

```
[7] def numbers(n):
    # Decision-making logic: Determines if 'n' is positive, negative, or zero.
    # No loops are present in this function; execution flows through conditional branches.
    # Check if 'n' is positive
    if n > 0:
        result = "Positive"
    # If not positive, check if 'n' is negative
    elif n < 0:
        result = "Negative"
    # If neither positive nor negative, 'n' must be zero
    else:
        result = "Zero"
    return result
numbers(3)

... 'Positive'
```

Task Description -3 (Documentation – File-Level Overview)

Code Used: def

```
factorial(n): result = 1
for i in range(1, n + 1):
    result *= i
return result
```

```
def square_list(numbers):
    return [n * n for n in numbers]
```

```
def main():
    print(factorial(5))
```

```
print(square_list([1, 2, 3, 4])) main()
```

Prompt:

Generate a high-level overview summarizing the overall purpose and functionality of the Code. add the summary at the beginning

Output:

```
[8] # This code defines two utility functions: `factorial` to calculate the factorial of a number,
✓ Os # and `square_list` to square each element in a list. It then demonstrates their usage in a `main` function.

def factorial(n):
    result = 1
    for i in range(1, n + 1):
        result *= i
    return result

def square_list(numbers):
    return [n * n for n in numbers]

def main():
    print(factorial(5))
    print(square_list([1, 2, 3, 4]))

main()

... 120
[1, 4, 9, 16]
```

Task Description -4 (Documentation – Refine Existing Documentation)

Code Used: def
calculate_discount(price, discount):
 # calculate if price
 > 0: # apply
 discount
 final_price = price - (price * discount / 100)
 return final_price
else:
 # wrong price
 return 0

Prompt:

Rewrite the documentation to improve clarity and consistency.

Output:

```
[10]
✓ 0s def calculate_discount(price, discount):
    """
    Calculates the final price after applying a discount.

    Args:
        price (float or int): The original price of the item.
        discount (float or int): The discount percentage to apply (e.g., 10 for 10%).

    Returns:
        float: The final price after applying the discount. Returns 0 if the original price is not positive.
    """
    if price > 0:
        # Apply the discount percentage to the original price
        final_price = price - (price * discount / 100)
        return final_price
    else:
        # Return 0 if the price is invalid (non-positive)
        return 0
```

Task Description -5 (Documentation – Prompt Detail Impact Study)

Code Used: def
reverse_string(text):
return text[::-1]

Prompt - 1:

Write a short documentation comment explaining what this Python function does.

Output - 1:

```
[12]
✓ 0s def reverse_string(text):
    """
    Reverses a given string.

    Args:
        text (str): The input string to be reversed.

    Returns:
        str: The reversed string.
    """
    return text[::-1]
```

Prompt - 2:

Write a clear and detailed documentation comment for the given Python function.

Output - 2:

```
[13]
✓ Os ▶ def reverse_string(text):
      """
      Reverses the given input string.

      This function takes a string as input and returns a new string
      with the characters in reverse order. It utilizes Python's string slicing
      feature to achieve this efficiently.

      Args:
          text (str): The input string that needs to be reversed.

      Returns:
          str: A new string containing the reversed characters of the input string.

      Examples:
          >>> reverse_string("hello")
          'olleh'
          >>> reverse_string("Python")
          'nohtyP'
          >>> reverse_string("12345")
          '54321'
      """
      return text[::-1]
```
